

JMP SPC Script That I Use Daily

The problem:

Companies often rely on outdated software for Statistical Process Control (SPC) to monitor manufacturing processes. Numerous other SPC programs are in use by industry, but companies often stick with legacy programs that make data analysis and presentation difficult for users. In this example below, only one tool (manufacturing machine, furnaces in this case) can be displayed at a time. Additionally, the user cannot easily browse through factors such as furnace processing zone, or metrology tool.

The solution:

The JMP script allows me to select the process recipe by typing the name into a popup window. It then joins the thickness data file to another file containing the limits for that file. Now all tools (furnaces in this case) are displayed on the same chart for quick comparison.

The script above shows the average thickness for all zones in the furnace. The chart below breaks the thickness down to individual zones. Now I can see if each zone is tuned to target or if it is stable.

The script also calculates the thickness range for each individual zone; so the user can highlight the specific area of the furnace causing the problem.

Measurement issues with metrology equipment can also be the cause of bad thickness results. Usually, the metrology tool is automatically entered with the correct spelling, but sometimes data is entered manually with incorrect spelling. For example, DA01FE is also DA01FEIV.

The script corrects for common misspellings.
